Payout policy

Companies can pay out cash to their shareholders in two ways

- dividend
- buy back outstanding shares

Miller & Modigliani dividend irrelevancy theorem (1961)

- Miller & Modigliani (1961) showed that whether earnings are paid out through dividends or share repurchases has no effect given the following assumptions apply:
 - No tax considerations nor transaction costs.
 - Investment, financing and operating policies are held fixed
- Granted that the assumptions above hold, the investors can undo the way in which the payout was handled

Does the theory hold

- Difference in tax treatment
- Informational content of dividends vs. share repurchases
 - Dividends: A firm reporting good earnings and paying a generous dividend is putting its money where its mouth is
 - Share repurchase: More one-off event. Signaling that you, the management, believe the stock is "cheap"

General points on payout policy

- In the absence of taxes, transaction costs and the signaling effect of paying dividends
 - Dividend payouts will increase or decrease the value of the company depending on whether or not there are NPV investments which could be funded with the retained earnings
- In general, companies should opt for share repurchases rather than dividends due to the preferential tax treatment of capital gains by tax-paying investors

Capital structure

- The firm's mix of debt and equity financing is called capital structure
- The job of the financial manager is to maximize the value of the firm by choosing the optimal combination of securities
- The proportion of the total assets of the firm financed through debt is known as financial leverage or gearing

Leverage ratios of various companies

Exhibit IV.2: Financial Ratios of Selected U.S. Corporation, 1993

Company Name	Debt Debt + Mkt Equity	Debt Total Book Assets	EBITDA Interest
Boeing	15	13	14.37
Boston Edison	49	42	3.49
John Deere	40	37	2.47
Delta Air Lines	53	32	1.08
Disney	9	20	14.09
General Motors	61	37	2.98
Hewlett-Packard	13	17	21.67
McDonalds	15	31	7.18
3M	6	12	59.70
Philip Morris	27	35	6.72
Raytheon	9	12	37.88
Safeway Stores	55	53	3.06
Техасо	27	26	4.70
Wal-Mart	14	36	7.54

Modigliani-Miller theorem (1958 & 1961)

- First to introduce a model on the optimal capital structure
- Somewhat surprising result:
 - M&M proposition I: The capital structure of a company has no effect on its value
 - No matter how you slice a pie, the size of the pie doesn't change

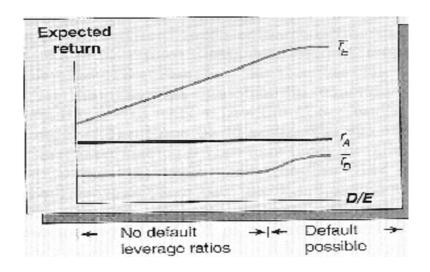

Modigliani-Miller theorem (1958 & 1961) - assumptions

- Assumptions of the model
 - Perfect capital markets
 - No taxes and no transaction costs
 - Bankruptcy exists but is costless
 - Ownership is simply transferred from shareholders to debtholders in the event of default
- Proof:
 - Based on a no arbitrage argument (refer to the numerical example in G&T)
 - Idea: Investors can undo the capital structure themselves and are therefore unwilling to pay a premium for leveraged companies

Modigliani and Miller

- Proposition I:
 - Financial leverage has no effect on shareholders' wealth
- Proposition II:
 - The expected rate of return on the common stock of a levered firm increases in proportion to the debt-equity ratio (D/E)
- How do these two propositions link
 - Any increase in expected return is exactly offset by an increase in risk and therefore the shareholders' required rate of return

Cost of capital

Relaxing the assumptions - corporate taxes

- ullet Same as before, however, the company must pay a tax of \mathcal{T}_c on its profits
 - Remember: corporate interest payments are a tax-deductible expense
- ullet Earnings Before Interest and Tax: \widetilde{X}
- Payoff to investors of the company:
 - Unlevered company

$$\widetilde{X}(1-T_c)$$

Levered company

$$\underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Debt holders}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Debt holders}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Debt holders}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Debt holders}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Debt holders}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Debt holders}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right) \left(1 - T_c\right)}_{\text{Taxable income}} + \underbrace{ \left(\widetilde{X} - r_D D\right)$$

Implications of corporate taxes

The value of the company is increasing in the amount of debt

ullet Adapted proposition I: value of firm = value of all-equity-financed firm + PV(tax shield)

Companies should increase their leverage until one of two things happen:

- They pay no tax
- They are completely debt financed

Contradicts what we see in practice, hence, something appears to be wrong

- Personal taxes
- Inability to use tax shield
- Bankruptcy costs

Including both corporate and personal taxes

It is no longer the firm's objective to minimize corporate taxes

they should try to minimize the present value of all taxes paid on corporate income (incl. personal taxes paid by bondholders and stockholders)

Or

Maximize after (total) tax income

Tax gain of leverage

$$T_{g} = 1 - \left[\frac{\left(1 - T_{c}\right)\left(1 - T_{E}\right)}{1 - T_{D}} \right]$$

- If $T_c = T_D = T_E = 0$ then $T_g = 0 \rightarrow$ the original model where taxes are irrelevant
- If $T_E = T_D \rightarrow T_g = T_c$ so the tax advantage is determined solely by the corporate tax rate
- If $T_g > 0$ the company will prefer to be completely debt financed. In the opposite case, equity financing will be preferred.

Capital structure when taxable earnings are low

- So far, we have assumed the firm can always utilize their interest tax shield.
 - This may not be the case.
 - Companies with low current earnings and/or high non-debt tax shields (R&D expenses, depreciation deductions)
 - Start up firms
 - General Motors (see 3. quarter 2007 earnings announcement)
